L11

(1)

Stable sorting

Radix Sort

Quick sort ← 6.006

Sorting races

## Stable Sorting

Preserves input order among equal elements

4'	1	3*	4	3
----	---	----	---	---

1	3*	3	4'	4
---	----	---	----	---

Counting sort is stable  
Merge sort is stable

Selection sort: Find maximum element and put it at end of array (swap with element at end of array)

Heap  
not stable!

$3 \begin{matrix} \curvearrowright \\ \curvearrowleft \end{matrix} 2_a \ 2_b \rightarrow 2_b \ 2_a \ 3$

define $2_a < 2_b$
-----------------------

# Radix Sort

(2)

- Herman Hollerith card-sorting machine for 1890 census

- Digit by Digit sort by mechanical machine

- 1) examine given column of each card in a deck
- 2) Distribute the card into one of 10 bins
- 3) Gather cards bin by bin, so cards with first place punched are on top of cards with second place punched, etc.

## MSB vs LSB?

Sort on most significant digit first or least significant digit first?

MSB strategy: Cards in 9 of 10 bins must be put aside, leading to a large number of intermediate piles

LSB strategy: Can gather sorted cards in bins appropriately to create a deck!

EXAMPLE

3	2	9
4	5	7
6	5	7
8	3	9
4	3	6
7	2	0
3	5	5

↑

7	2	0
3	5	5
4	3	6
4	5	7
6	5	7
3	2	9
8	3	9

↑

7	2	0	3	2	9	
3	2	9	3	5	5	
4	3	6	→	4	3	6
8	3	9	→	4	5	7
3	5	5		6	5	7
4	5	7		7	2	0
6	5	7		8	3	9

Digit sort needs to be stable, else will get wrong result!

Analysis

Assume counting sort is auxiliary stable sort.  $\Theta(n+k)$  complexity

Suppose we have  $n$  words of  $b$  bits each.

One pass of counting sort  $\Theta(n+2^b)$

$b$  passes of counting sort  $\Theta(b(n+2^b)) = \Theta(nb)$

$\frac{b}{r}$  passes  $\Theta(\frac{b}{r}(n+2^r))$   
minimized when  $r = \lg n$   $\Theta(\frac{bn}{\lg n})$

# QUICKSORT

"enrichment"

Divide : partition the array into two sub arrays around a pivot  $x$  such that elements in lower sub array  $\leq x \leq$  elements in upper sub array.  $\leftarrow$  Linear time

Conquer : Recursively sort the two subarrays

Combine : Trivial.

If we can choose a pivot such that two sub arrays are roughly equal

$$T(n) = 2T(n/2) + \theta(n)$$

$$\Rightarrow T(n) = \theta(n \lg n)$$

If one array is much bigger

$$T(n) = T(n-1) + \theta(n)$$

$$\Rightarrow T(n) = \theta(n^2)$$

Average case  $\theta(n \lg n)$  assuming input array is randomized!

# Sorting Races

<http://cg.scs.carleton.ca/~morin/misc/sortalg>

Bubble sort : Repeatedly step thru list to be sorted. Compare 2 items, swap if they are in the wrong order. Continue thru list, until no swaps. Repeat pass thru list until no swaps

$\Theta(n^2)$

Shell sort : Improves insertion sort by comparing elements separated by gaps

$\Theta(n \log^2 n)$

Bubble sort vs. Insertion sort  
last element put in place each element put in right place

Heap sort vs. Merge sort vs. QuickSort
