

Virtual Pet

ChengHau Tong

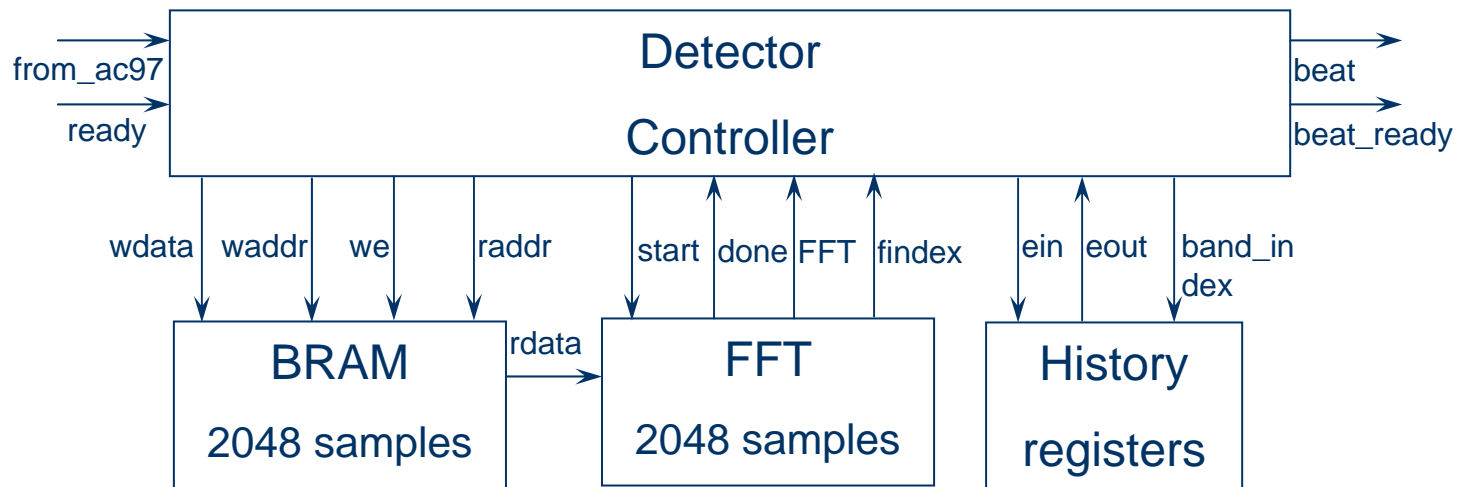

Overview

- A virtual pet that lives inside the LCD display.
- It listens to music and dances to it.
- When it dances, the lights in the LCD display flash according to the music beat.
- When it is idle, the lights express its emotion.
- Music makes it stay happy and alive.
- 2 main components:-beat detector and video.

Beat detection

- A beat is a variation in the strength of audio signal.
- Feed 2048 samples (at frequency 48khz) into FFT.
- Break the frequency range into 32 subbands, and calculate the energy of the subbands.
- Compare the energy of the subbands to the average energy of the subband in past one second.
- If $\text{Current Energy} > c * \text{Average Energy in past one second}$, a beat is detected.

Beat Detector Block Diagram

Video Modules

- 4 video modules of fixed pixel locations
 - Dancing dog
 - Idle dog
 - Health Meter
 - Lights
- Main FSM controls the video modules.

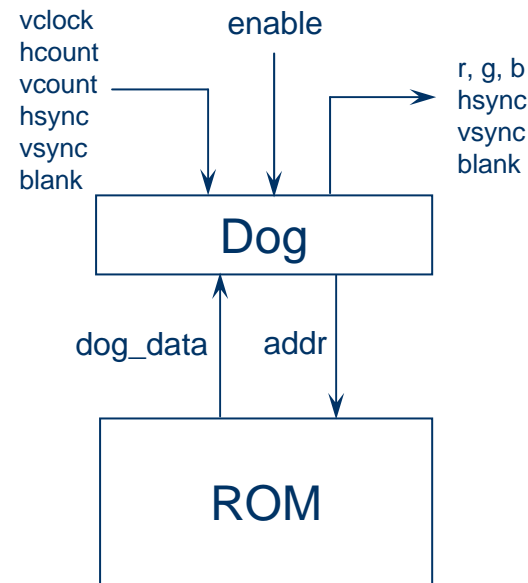

Main FSM

- Initial state is idle—Lights show emotion, Idle dog video module is active.
- When a beat is detected, FSM changes to dancing state—Lights flash according to music beat, Dancing dog video module is active.
- Determine the health and emotion of the pet, based on the amount of music played and when music was last played.
- If there is no beat after a certain amount of time, Main FSM switches back to Idle state.

Dog Modules (Idle and Dancing)

- Retrieve video data from ROM when activated.
- ROM is 24-bit wide to store the values of 3 colors at each pixel.
- Address to ROM increases everytime vcount increases.

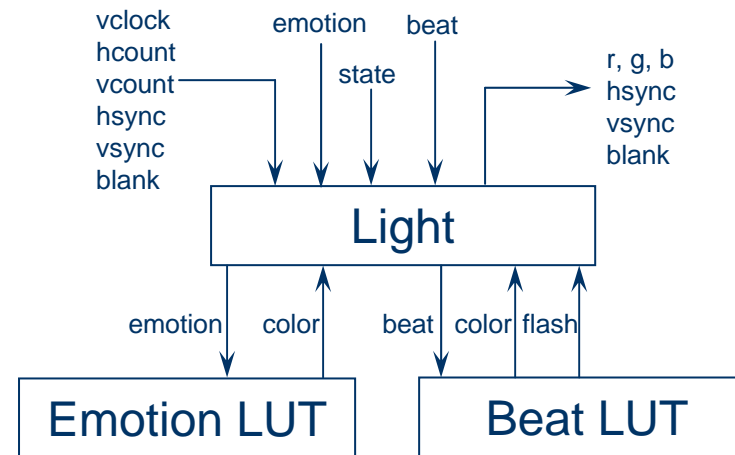

Health Meter

- Health Point determines the color and the length of health meter.
- Health meter video module draws the health meter based on the health point from Main FSM.

Lights

- In Idle state, emotion determines the color of the lights.
- In Dancing state, beat determines the color of the lights and whether they flash.
