

Fully Homomorphic Encryption and Post Quantum Cryptography

6.857

Lecture 14

Post Quantum Cryptography

All the **assumptions** that we
have seen so far for public
key cryptography are
broken using **quantum
computers**

Factoring, RSA, Discrete Log, Elliptic Curves...

Is Crypto Going to Die??

- There is a family of assumptions that are believed to **resist quantum attacks**.
- We know how to **build crypto-systems** from these assumptions. 

Today

1. Define **Learning with Error** (LWE) assumption, which is believed to be post-quantum secure
2. **Fully Homomorphic Encryption** (FHE)
 - Definition
 - Application
 - Construction from LWE

Learning with Error (LWE)

[Regev 2004]

LWE assumption: It is **hard** to solve
random noisy linear equations

Note: It is easy to solve linear equations without noise (Gaussian Elimination)

Learning with Error (LWE)

[Regev 2004]

Formally: LWE is associated with parameters
 (q, n, m, χ)

q = field size (prime)

n = # variables

m = # equations ($m \gg n$)

χ = error distribution

$LWE_{q,n,m,\chi}$: For random $s \leftarrow Z_q^n$, random $A \leftarrow Z_q^{n \times m}$, and $e \leftarrow \chi^m$,

$$(A, As + e) \approx (A, U)$$

$LWE_{q,n,m,\chi}$: For random $s \leftarrow Z_q^n$, random $A \leftarrow Z_q^{n \times m}$, and $e \leftarrow \chi^m$,

$$(A, As + e) \approx (A, U)$$

1. Believed to resist quantum attacks.
2. No known sub-exponential algorithms.
3. Reduces to worst-case lattice assumptions
4. Resilient to leakage
5. We can construct amazing cryptographic primitives from it, such as **fully homomorphic encryption!**

Fully Homomorphic Encryption

- Notion suggested by Rivest-Adleman-Dertouzos in 1978:

$$Enc(pk, x), Enc(pk, y) \xrightarrow{\text{easy}} Enc(pk, x + y)$$

$$Enc(pk, x), Enc(pk, y) \xrightarrow{\text{easy}} Enc(pk, x \cdot y)$$

- **First construction** by Gentry 2007 (lattice based).
- **First construction under LWE** by Brakerski and Vaikuntanathan 2011.
- **Today:** We will see construction by Gentry-Sahai-Waters 2013

Fully Homomorphic Encryption

- Notion suggested by Rivest-Adleman-Dertouzos in 1978:

$$Enc(pk, x), Enc(pk, y) \xrightarrow{\text{easy}} Enc(pk, x + y)$$

$$Enc(pk, x), Enc(pk, y) \xrightarrow{\text{easy}} Enc(pk, x \cdot y)$$

- Note: RSA and El-Gamal are homomorphic w.r.t. multiplication, but not addition:

$$\text{RSA: } x^e \bmod n, y^e \bmod n \xrightarrow{\text{easy}} (xy)^e \bmod n$$

$$\text{El-Gamal: } (g^{r_1}, g^{r_1 s} \cdot x), (g^{r_2}, g^{r_2 s} \cdot y) \xrightarrow{\text{easy}} (g^{r_1+r_2}, g^{(r_1+r_2)s} \cdot xy)$$

Applications of FHE: Private Delegation

- Suppose we want to delegate our computation (say to the cloud)
- Suppose we don't want the cloud to know what the computation is.

Can do private delegation using FHE!

Construction

[Gentry-Sahai-Waters13]

Gen(1^n): $A \leftarrow \mathbb{Z}_q^{(n-1) \times m}$ $m = \theta(n \log q)$

$s \leftarrow \mathbb{Z}_q^{n-1}$

$e \leftarrow \chi^m$

$PK = B = \begin{pmatrix} A \\ sA + e \end{pmatrix} \in \mathbb{Z}_q^{n \times m}$

$SK = t = (-s, 1) \in \mathbb{Z}_q^n$

$tB \approx 0$

Enc(PK, b): Choose at random $R \leftarrow \{0,1\}^{m \times N}$, output

$$CT = BR + bG \in \mathbb{Z}_q^{n \times N},$$

where $G \in \mathbb{Z}_q^{m \times N}$ is a fixed matrix

$$N = n(\log q + 1)$$

Dec(SK, CT): Compute $t \cdot CT$, and output 0 iff $t \cdot CT \approx 0$.

Correctness relies on the fact that R is small, and $t \cdot G$ is large:

$$t \cdot CT = t \cdot BR + btG \approx 0 + btG.$$

Construction

[Gentry-Sahai-Waters13]

Gen(1^n): $A \leftarrow \mathbb{Z}_q^{(n-1) \times m}$ $m = \theta(n \log q)$

$s \leftarrow \mathbb{Z}_q^{n-1}$

$e \leftarrow \chi^m$

$PK = B = \begin{pmatrix} A \\ sA + e \end{pmatrix} \in \mathbb{Z}_q^{n \times m}$

$SK = t = (-s, 1) \in \mathbb{Z}_q^n$

$tB \approx 0$

Enc(PK, b): Choose at random $R \leftarrow \{0,1\}^{m \times N}$, output

$$CT = BR + bG \in \mathbb{Z}_q^{n \times N},$$

where $G \in \mathbb{Z}_q^{m \times N}$ is a fixed matrix

$$N = n(\log q + 1)$$

Security: If B was random in $\mathbb{Z}_q^{n \times m}$ then $(B, BR) \equiv (B, U)$
(by the **Leftover Hash Lemma**, follows from the fact that $m > n \log q$).
→ By LWE, $(B, BR) \approx (B, U)$

Construction

[Gentry-Sahai-Waters13]

Enc(PK, b): Choose at random $R \leftarrow \{0,1\}^{m \times N}$, output

$$CT = BR + bG \in \mathbb{Z}_q^{n \times N},$$

where $G \in \mathbb{Z}_q^{m \times N}$ is a fixed matrix

$$N = n(\log q + 1)$$

$$\underbrace{BR_1 + b_1G}_{CT_1}, \underbrace{BR_2 + b_2G}_{CT_2} \xrightarrow{\text{easy}} CT^+ = CT_1 + CT_2 = B(R_1 + R_2) + (b_1 + b_2)G$$

mod q, we want mod 2

$$CT_1, CT_2 \xrightarrow{\text{easy}} CT^\times = CT_1 \cdot \underbrace{G^{-1}(CT_2)}_{\text{in } \{0,1\}^{N \times N}} = (BR_1 + b_1G) \cdot G^{-1}(CT_2) \\ = BR' + b_1 \cdot CT_2 = BR'' + b_1b_2G$$

Can get addition mod 2 by computing $CT^+ - 2CT^\times$

The Error Grows!

$$\underbrace{BR_1 + b_1G}_{CT_1}, \underbrace{BR_2 + b_2G}_{CT_2} \xrightarrow{\text{easy}} CT^+ = CT_1 + CT_2 = B(R_1 + R_2) + (b_1 + b_2)G$$

$$CT_1, CT_2 \xrightarrow{\text{easy}} CT^\times = CT_1 \cdot \underbrace{G^{-1}(CT_2)}_{\text{in } \{0,1\}^{N \times N}} = (BR_1 + b_1G) \cdot G^{-1}(CT_2) \\ = BR' + b_1 \cdot CT_2 = BR'' + b_1 b_2 G$$

**Bootstrap to reduce
the noise!**
