6.890	Lecture 10	Oct. 7, 2014

<u>Optimization problem</u>: (combinatorial)
- <u>goal</u>: instance → <u>solution</u> with min/max cost
  - set of instances
  - for each instance:
    - set of (valid/feasible) solutions
    - nonnegative <u>cost</u> of each solution ($\mathbb{R}$ or $\mathbb{Z}$)
  - <u>objective</u>: min or max

<u>OPT</u>(x) = min/max possible cost for instance x
(sometimes also the solution itself)

<u>NP optimization problem</u>:
- solutions have polynomial length
- instances & their solutions can be recognized $\in P$
- cost function $\in P$

⇒ <u>decision problem</u> $\in NP$
↳ min: is $OPT(x) \leq q$? ($\geq \in coNP$)
max: is $OPT(x) \geq q$? ($\leq \in coNP$)

<u>NPO</u> = {NP optimization problems}

Approximation: ALG is a c-approximation if $\forall x$:
instance

- min: $\dfrac{\text{cost}(\text{ALG}(x))}{\text{cost}(\text{OPT}(x))} \le c$ $(c \ge 1)$
- max: $\dfrac{\text{cost}(\text{OPT}(x))}{\text{cost}(\text{ALG}(x))} \le c$ $(c \ge 1)$ e.g. 2

  OR: $\dfrac{\text{cost}(\text{ALG}(x))}{\text{cost}(\text{OPT}(x))} \ge c$ $(c \le 1)$ e.g. $\frac{1}{2}$
- usually: ALG should be polynomial time

PTAS (Polynomial-Time Approximation Scheme)

= algorithm with additional input $\varepsilon > 0$

- solution is $(1+\varepsilon)$-approximation
- polynomial time for every fixed $\varepsilon > 0$
  - e.g. $n^{2^{1/\varepsilon}}$ OK (tighter notions later)

PTAS = {NP optimization problems having PTAS}

$= \bigcap_{c>1} c\text{-APX}$

F-APX = {NP optimization problems having poly-time $f(n)$-approximation algorithm for some $f \in F$}

APX $= O(1)$-APX

= MAX SNP in older literature

Log-APX $= O(\lg n)$-APX

Poly-APX $= n^{O(1)}$-APX

- $P \ne NP \Rightarrow \text{PTAS} \subsetneq \text{APX} \subsetneq \text{Log-APX} \subsetneq \text{Poly-APX}$ etc.

Typical approximation factors: (graph problems)

- $1+\varepsilon$ (PTAS)
  - lots of problems on planar/H-minor-free graphs
    e.g. H-minor-free dominating set
    choose min. # vertices adjacent to unchosen vertices
  - & in Euclidean plane e.g. TSP,
    Steiner tree, rectilinear Steiner tree [L9]
- $\Theta(1)$ (APX-complete)
  - lots e.g. TSP, Steiner tree
  - max. coverage: choose k vertices from left side of bipartite graph adjacent to max. # vertices
    "dual"
- $\Theta(\log^* n)$
  - asymmetric k-center: given asymmetric metric, choose k vertices to min. max distance v→nearest chosen
- $\Theta(\log n)$
  - set cover & dominating set
    ↳ dominating set from left side of bipartite graph
  - max. unique coverage (exactly 1 left adjacent to right)

- $\Theta(\log^2 n)$
  - group Steiner tree: given graph & k groups of vertices, choose min. # vertices inducing connected subgraph & containing at least 1 vertex in each group
- $\Omega(\log^2 n) \cap O(n^\varepsilon)$ (OPEN)
  - directed Steiner tree: given graph, k terminal vertices, & root vertex, choose min. # vertices inducing root-to-terminal path for each terminal
- $\Omega(2^{\log^{1-\varepsilon} n}) \cap O(n^c)$ (OPEN)
  - $c = \frac{1}{3}$ → label cover (MinRep & MaxRep) [future lecture]
  - $c = \frac{4}{5} + \varepsilon$ → directed Steiner forest: given $s_i \to t_i$ pairs, choose min. # vertices inducing such paths
- $\Omega(n^{1-\varepsilon}) \cap \tilde{O}(n)$

  polylog factors

  - chromatic number: min k such that k-colorable
  - independent set ≡ clique (complement graph)

Approximation preserving reductions: $A \to B$

(see Crescenzi — CCC 1997)

A instance x $\xrightarrow{f}$ B instance $x' = f(x)$

A solution $y = g(x, y')$ to x $\xleftarrow{g}$ B solution y' to x'

PTAS-reduction: $\forall \varepsilon > 0 \ \exists \delta = \delta(\varepsilon) > 0$ such that

y' is $(1+\delta(\varepsilon))$-approximation to B

$\Rightarrow y = g(x, y')$ is $(1+\varepsilon)$-approximation to A

[Crescenzi & Trevisan 1994]

- f & g can depend on ε too (else "P-reduction")
- $B \in PTAS \Rightarrow A \in PTAS$ (chain algs. together)
- $A \notin PTAS \Rightarrow B \notin PTAS$
- ditto for APX
- careful: $A \in PTAS \not\Rightarrow B \in PTAS$
- if $\delta(\emptyset) = \emptyset$ also works then also NP reduction
- reductions chain: $A \to B \to C$

AP-reduction: $\delta(\varepsilon) = O(\varepsilon)$ ($\leq c \cdot \varepsilon$, no growth assumption) [Crescenzi, Kann, Silvestri, Trevisan 1995]

- $B \in O(f)\text{-APX} \Rightarrow A \in O(f)\text{-APX}$

Strict reduction: $\delta(\varepsilon) = \varepsilon$ [Orponen & Mannila 1987]

APX-hard = ∃PTAS-reduction from any problem ∈ APX
- $\notin$ PTAS if $P \neq NP$

$O(f)$-APX-hard = ∃ AP-reduction from any problem $\in O(f)$-APX
(other definitions possible)
- $\notin o(f)$-APX if $P \neq NP$

L-reduction: $OPT_B(x') = \overset{\leq \alpha \cdot}{O}(OPT_A(x))$
& $|cost_A(y) - OPT_A(x)| = \underset{\leq \beta \cdot}{O}(|cost_B(y') - OPT_B(x')|)$
[Papadimitriou & Yannakakis - JCSS 1991]

$\Rightarrow$ PTAS-reduction
- for minimization problems:
  $\Rightarrow$ AP-reduction with $\delta(\varepsilon) = \varepsilon / \alpha\beta$:

$$\frac{cost_A(y)}{OPT_A(x)} \leq \frac{OPT_A(x) + \beta(cost_B(y') - OPT_B(x'))}{OPT_A(x)}$$
$$\leq 1 + \alpha\beta\left(\frac{cost_B(y') - OPT_B(x')}{OPT_B(x')}\right)$$
$$= 1 + \alpha\beta\left(\underbrace{\frac{cost_B(y')}{OPT_B(x')}}_{\leq 1 + \delta(\varepsilon) = 1 + \varepsilon/\alpha\beta} - 1\right)$$
$$\leq 1 + \varepsilon. \quad \square$$

- also NP reduction
- most popular reduction type

L-reduction → PTAS-reduction, max case: (uncovered)

$$\mathrm{cost}_A(y) = \mathrm{OPT}_A(x) - \underbrace{(\mathrm{OPT}_A(x) - \mathrm{cost}_A(y))}_{\leq \beta \cdot (\mathrm{OPT}_B(x') - \mathrm{cost}_B(y'))}$$

$$\geq \mathrm{OPT}_A(x) - \beta(\mathrm{OPT}_B(x') - \mathrm{cost}_B(y'))$$

$$\frac{\mathrm{cost}_A(y)}{\mathrm{OPT}_A(x)} \geq \frac{\mathrm{OPT}_A(x) - \beta(\mathrm{OPT}_B(x') - \mathrm{cost}_B(y'))}{\mathrm{OPT}_A(x)}$$

$$= 1 - \beta\,\frac{\mathrm{OPT}_B(x') - \mathrm{cost}_B(y')}{\mathrm{OPT}_A(x)}$$

$\mathrm{OPT}_B(x') \leq \alpha \cdot \mathrm{OPT}_A(x)$

$\mathrm{OPT}_A(x) \geq \frac{1}{\alpha}\mathrm{OPT}_B(x')$

$\frac{1}{\mathrm{OPT}_A(x)} \leq \alpha \frac{1}{\mathrm{OPT}_B(x')}$

$-\frac{1}{\mathrm{OPT}_A(x)} \geq -\alpha \frac{1}{\mathrm{OPT}_B(x')}$

$$\geq 1 - \alpha\beta\,\frac{\mathrm{OPT}_B(x') - \mathrm{cost}_B(y')}{\mathrm{OPT}_B(x')}$$

$$= 1 - \alpha\beta\Big(1 - \underbrace{\frac{\mathrm{cost}_B(y')}{\mathrm{OPT}_B(x')}}_{\geq \frac{1}{1+\delta}}\Big)$$

$$\geq 1 - \alpha\beta + \frac{\alpha\beta}{1+\delta}$$

$$= \frac{1}{1+\varepsilon} \text{ when } \delta = \frac{1}{\alpha\beta(1+\frac{1}{\varepsilon}) - 1} = \frac{\varepsilon}{\alpha\beta} \Big/ \left(1 + \varepsilon - \frac{\varepsilon}{\alpha\beta}\right)$$

$$1+\delta = \frac{\alpha\beta(1+\frac{1}{\varepsilon})}{\alpha\beta(1+\frac{1}{\varepsilon}) - 1} \qquad \frac{1}{1+\delta} = \frac{\alpha\beta(1+\frac{1}{\varepsilon}) - 1}{\alpha\beta(1+\frac{1}{\varepsilon})}$$

$$\frac{\alpha\beta}{1+\delta} + 1 = \frac{\alpha\beta(1+\frac{1}{\varepsilon}) + \frac{1}{\varepsilon}}{1+\frac{1}{\varepsilon}} \qquad \frac{\alpha\beta}{1+\delta} + 1 - \alpha\beta = \frac{\frac{1}{\varepsilon}}{1+\frac{1}{\varepsilon}} = \frac{1}{\varepsilon+1}$$

CLEANER: y' is a $(1 - \varepsilon/\alpha\beta)$-approximation
$\Rightarrow y$ is a $(1-\varepsilon)$-approximation ($c < 1$ view)

[Williamson & Shmoys book, 2010]

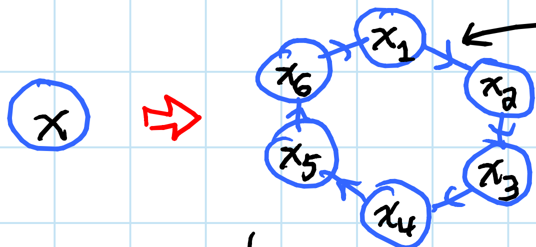
APX-complete problems:

Max E3SAT-E5: exactly 3 distinct literals/clause & exactly 5 occurrences/variable

[Feige – J.ACM 1998]

Max 3SAT-3: [Papadimitriou & Yannakakis – JCSS 1991]

- usual 3SAT → 3SAT-3 reduction:



$\neg x_1 \vee x_2$

i.e. $x_1 \Rightarrow x_2$

  - not approximation preserving: can now set variable x half true & half false at cost of one violation (can't bound damage)
- fix: connect copies $x_1, x_2, \ldots, x_k$ with an expander graph where edge is $x_i = x_j$ $\left(\begin{matrix}\neg x_i \vee x_j \\ \neg x_j \vee x_i\end{matrix}\right)$
  - ↳ bounded degree, k nodes
  - ↳ $\forall$ cut (A, B): # cross edges $\geq \min\{|A|, |B|\}$

  (simplification of PY91 construction by Crescenzi 1997)

  $\Rightarrow$ setting x_i's to majority value won't decrease # satisfied clauses

$\Rightarrow$ 3SAT-$O(1)$ is APX-hard

↳ $29 = 2 \cdot 14 + 1$ using 14-regular expander

[Lubotzky, Phillips, Sarnak – Combinatorica 1988]

- then use usual reduction → 3SAT-3

  $O(k)$ violations $\Leftarrow$ k violations

$\Rightarrow$ L-reduction actually a gap reduction, not L reduction ☹

Independent set, max. degree $\Delta = O(1)$

- any maximal indep. set is Δ-approximation
- strict-reduction from Max 3SAT-3
  [Papadimitriou & Yannakakis – JCSS 1991]
  - variable gadget ⇒ indep. set can't use x_i & $\bar{x}_i$
  - clause gadget ⇒ ≤ 1 point, 0 if not satisfied
  - max. degree 4
- 3-regular also APX-complete [Berman & Fujito – TCS 1999] & [Alimonti & Kann – TCS 2000]

Vertex cover

- greedy algorithm is 2-approximation
- L-reduction from Independent set: do nothing
  [Papadimitriou & Yannakakis – JCSS 1991]
  - vertex cover ⇔ complement is independent
  - OPT_{VC} & OPT_{IS} both $\Theta(|V|)$ for bounded-degree graphs ⇒ Θ(each other)
  - absolute error preserved
- 3-regular OK

Dominating set, max. degree $\Delta = O(1)$

- any mimimal dominating set is Δ-approximation
- strict-reduction from Vertex cover:
  [Papadimitriou & Yannakakis – JCSS 1991]

  ⇒ never need to choose edge node (move → v)
- 3-regular OK
